# Introduction

Introduktion til hele projektet, skal kunne læses som en appetitvækker til resten af rapporten, det vi skriver her skal så uddybes senere. Brug dog stadigvæk kilder.

- kort intro a EEG og den brede anvendelse, anvendelse indenfor høreapparat.
- intro af model, problem med overbestemt system
- Seneste forslag til at løse dette
- vi vil efterviser dette og udvide til realtime tracking
- opbygningen af rapporten

# Chapter 1

## Problem Analysis

This chapter examines existing literature concerning source localisation from EEG measurements. At first a motivation for the problem is given, considering especially the application within the hearing aid industry. Further, the state of the art methods are presented followed by a description of the contribution proposed in this thesis.

### 1.1 Motivation

(Hvad er EEG)

EEG recordings or measurements are used within medicine as an imaging technique measuring electric signals on the scalp, caused by brain activity.

The brain consist of an enormous amounts of cells, called neurons. These neurons are mutually connected in neural nets and when a neuron is activated, for instance by some physical stimuli, local current flows are produced[3]. As such the neurons are somehow communicating(?).

The EEG measurements are provided by a varies number of metal electrodes referred to as sensors, placed on the scalp of a human reading electrical signals which are massively amplified and displayed on the computer as a sum of sinusoidal waves relative to time.

It takes a large amount of active neurons to generate an electrical signal that is recordable on the scalp as the current then have to penetrate the skull, skin and several other thin layers.

From this it is clear that the measurements from a single sensor do not correspond to the activity of a single neuron in the brain, but rather a collection of many activities. Here the same neuron activities can be measured by two or more sensors. Furthermore, interfering signals can occur resulting from physical movement of e.g. eyes and jawbone[3].

The waves resulting from EEG have been classified into four groups according to the dominant frequency. The delta wave (0.5 – 4 Hz) is observed from infants and sleeping adults, the Theta wave (4 – 8 Hz) is observed from children and sleeping adults, the alpha wave (8 – 13 Hz) is the most extensively studied brain rhythm, which is induced by an adult laying down with closed eyes. Lastly the beta wave (13 – 30 Hz) is considered the normal brain rhythm for normal adults, associated with active thinking, active attention or solving concrete problems[1, p. 11]. An example of EEG measurement within the four categories are illustrated by figure 1.1. Evoked

**Figure 1.1:** Example of time dependent EEG measurements within the four defined categories alpha, beta, theta and delta. Image source: [1]

potential

(Hvad bruges det til)

EEG is widely used within medicine and research of the cognitive processes in the brain. Diagnosis and Management of neurological disorders such as epilepsy is one example.

A great advantage of EEG is the speed. Neural activity can be measured within fractions of a second after a stimuli has been provided[3, p. 3]. When a person is exposed to certain stimuli, e.g. visual or audible, the measured activity is said to result from evoked potential.

(Hvad er problemet, localisation)

noter - den skal drejes hen på connectivity som et ønsket område, og dermed source lokalisation

- study of dynamical behaviour of the brain, now big research field because of EEG and others -> many data analysis tools

- lately functional integration is of interest that is interplay between functionally segregate brain areas

(Anvendelse i praksis)

evt. lave subsections her..

## 1.2 Related Work and Our Contribution

indhold

nb. husk at dette kapitel skal vise et helt system og hvorhenne i det system vi kigger nærmere og kommer ind med vores bidrag. Det skal gøres klar hvilke områder vi vælger at ligge vores kræfter i.

## Chapter 2

# Sparse Signal Recovery

Through this chapter an introduction to the concept compressive sensing is described with associated theory which later on will be used in the development of the algorithm with used methods known from compressive sensing to estimate the mixing matrix  $A$  and the sparse source matrix  $X$ .

### 2.1 Compressive Sensing

Compressive sensing is the theory of efficient recover/reconstruct a signal from minimal measurements. This recovery is often described as a linear model/system

$$\mathbf{y} = \mathbf{A}\mathbf{x},$$

which consist of observed data  $\mathbf{y} \in \mathbb{R}^M$ , a matrix  $\mathbf{A} \in \mathbb{R}^{M \times N}$  which models the linear measurements and signal  $\mathbf{x} \in \mathbb{R}^N$ . In compressive sensing terminology,  $\mathbf{y}$  is the signal of interest that is wish recovered from minimal measurements meaning that the signal  $\mathbf{x}$  must be sparse.

A signal is said to be  $k$ -sparse if the signal has at most  $k$  non-zeros coefficient

$$\|\mathbf{x}\|_0 = \text{card}(\text{supp}(\mathbf{x})) \leq k,$$

where the  $\ell_0$ -norm is used. The function  $\text{card}$  is the cardinality of the support of  $\mathbf{x}$ . The support of  $\mathbf{x}$  is giving as

$$\text{supp}(\mathbf{x}) = \{j \in [N] : x_j \neq 0\},$$

where  $[N]$  a set [2, p. 41]. The set of all  $k$ -sparse signals is denoted as

$$\Sigma_k = \{\mathbf{x} : \|\mathbf{x}\|_0 \leq k\}.$$

It is of interest to recover the signal  $\mathbf{y}$  when  $M \ll N$  and  $k < M$  [4, p. 8]. This lead to that the matrix  $\mathbf{A}$  becomes rank-deficient and therefore have a non-empty

null-space [4, p. ix].

The linear model and finding the sparse signal  $\mathbf{x}$  can be written as an optimisation problem

$$\min_{\mathbf{z}} \|\mathbf{z}\|_0 \quad \text{s.t.} \quad \mathbf{y} = \mathbf{Az},$$

where  $\mathbf{z}$  is all possible candidates to an  $k$ -sparse signal  $\mathbf{x}$ .

Unfortunately, this optimisation problem is non-convex because of  $\ell_0$ -norm and is therefore difficult to solve – it is a NP-hard problem. Instead by replacing the  $\ell_0$ -norm with its convex approximation, the  $\ell_1$ -norm, the optimisation problem become computational feasible [4, p. 27]

$$\min_{\mathbf{z}} \|\mathbf{z}\|_1 \quad \text{s.t.} \quad \mathbf{y} = \mathbf{Az}, \quad (2.1)$$

and instead we find the best  $k$ -term approximation of the signal  $\mathbf{x}$ .

### 2.1.1 Conditions on the Mixing Matrix

To ensure an exact or an approximate reconstruction of the sparse signal  $\mathbf{x}$  some conditions associated on the matrix  $\mathbf{A}$  must be satisfied.

#### Null Space Conditions

The null space property (NSP) is some necessary and sufficient condition for exact recovery. The null space of the matrix  $A$  is defined as

$$\mathcal{N}(A) = \{z : Az = 0\}.$$

#### Restricted Isometry Conditions

NSP do not take account for noise and we must therefore look at some stronger conditions which incorporate noise, the following restricted isometry property (RIP)

##### Definition 2.1 (Restricted Isometry Property)

A matrix  $A$  satisfies the RIP of order  $k$  if there exists a  $\delta_k \in (0, 1)$  such that

$$(1 - \delta_k) \|x\|_2^2 \leq \|Ax\|_2^2 \leq (1 + \delta_k) \|x\|_2^2,$$

holds for all  $x \in \Sigma_k$

If a matrix  $A$  satisfy RIP then it will also satisfy the NSP as RIP is strictly stronger than NSP.

**Theorem 2.1.1**

If  $A$  satisfies the RIP of order  $2k$  with the constant  $\delta_{2k} < \sqrt{2} - 1$ . Then

$$C = \frac{2}{1 - (1 + \sqrt{2})\delta_{2k}}$$

**Coherence**

The NSP provide a unique solution to the optimisation problem, (2.1), but is unfortunately complicated to investigate. Instead an alternative measure used for sparsity is presented.

Coherence is a measure of quality and determine if the matrix  $A$  is a good choice for the optimisation problem (2.1). A small coherence describe the performance of a recovery algorithm as good with that choice of  $\mathbf{A}$ .

**Definition 2.2 (Coherence)**

Coherence of the matrix  $A \in \mathbb{R}^{M \times N}$ , denoted as  $\mu(A)$ , with columns  $\mathbf{a}_1, \dots, \mathbf{a}_N$  for all  $i \in [N]$  is given as

$$\mu(A) = \max_{1 \leq i < j \leq n} \frac{|\langle a_i, a_j \rangle|}{\|a_i\|_2 \|a_j\|_2}.$$

**2.2 ICA**

Through this section the mathematical concepts of Independent Component Analysis (ICA) will be explained and defined.

Lets set up an situations. We have some measurements that has been affect by some surrounding noise or "sideløbende" measurements such as different conversations in a room. The measurements can be described by a vector  $\mathbf{y}$  if we look at the one-dimensional case.  $\mathbf{y}$  consist of the measurement from the original signal, a vector  $\mathbf{x}$  and surrounding measurements, a matrix  $\mathbf{A}$ . This situation can be described as the linear model

$$\mathbf{y} = \mathbf{A}\mathbf{x} = \sum_{i=1}^n \mathbf{a}_i x_i$$

We known the measurements  $\mathbf{y}$  but if also knew the mixing parameter in  $\mathbf{A}$  then by inverting the linear model we could solve the system and find the original signal. But this is not the case as the mixing matrix also is unknown.

If we used the statistical properties of  $\mathbf{x}$  then it would be possible to estimate both the mixing matrix and then the original signal. What ICA do is to assume statistical independence

Lets define the ICA model which is a generative model meaning that the observed data is generated by a process of mixing components which are latent component. Let  $n$  be the observed random variables such that  $y_1, \dots, y_n$  are model as a linear combination of the random variables  $x_1, \dots, x_n$ :

$$y_i = a_{i1}x_1 + a_{i2}x_2 + \dots + a_{in}x_n, \quad i = 1, \dots, n$$

$$\mathbf{y} = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \dots & \vdots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{bmatrix} \mathbf{x}$$

where  $\mathbf{y} = \{y_i\}_{i \in [1, n]}$  and  $\mathbf{x} = \{x_t\}_{t \in [1, n]}$ . Furthermore,  $\mathbf{x}$  is statistically mutually independent.

Notes: ICA can be used on gaussian variables as little is done in addition to decorrelate for gaussian variable

Whiting is useful to be done beore ICA
